[Applicable PDU range test and calculation for window-based polling]

Background of Invention

[0001] 1. Field of the Invention

[0002] The present invention relates to a wireless communications protocol. More specifically, the present invention discloses a method and system that properly triggers a polling operation for a transmitter to request a receiving status of a receiver.

[0003] 2. Description of the Prior Art

[0004] Many communications protocols typically utilize a three-layered approach to communications. Please refer to Fig.1. Fig.1 is a block diagram of the three layers in such a communications protocol. In a typical wireless environment, a first station 10 is in wireless communications with one or more second stations 20. An application 13 on the first station 10 composes a message 11 and has it delivered to the second station 20 by handing the message 11 to a layer 3 interface 12. The layer 3 interface 12 may also generate layer 3 signaling messages 12a for the purpose of controlling layer 3 operations between the first station 10 and the second station 20. An example of such a layer 3 signaling message is a request for ciphering key changes, which are generated by the layer 3 interfaces 12 and 22 of both the first and the second stations, respectively. The layer 3 interface 12 delivers either the message 11 or the layer 3 signaling message 12a to a layer 2 interface 16 in the form of layer 2 service data units (SDUs) 14. The layer 2 SDUs 14 may be of any length. The layer 2 interface 16 composes the SDUs 14 into one or more layer 2 protocol data units (PDUs) 18.

Each layer 2 PDU 18 is of a fixed length, and is delivered to a layer 1 interface 19. The layer 1 interface 19 is the physical layer, transmitting data to the second station 20. The transmitted data is received by the layer 1 interface 29 of the second station 20 and reconstructed into one or more PDUs 28, which are passed up to the layer 2 interface 26. The layer 2 interface 26 receives the PDUs 28 and from them assembles one or more layer 2 SDUs 24. The layer 2 SDUs 24 are passed up to the layer 3 interface 22. The layer 3 interface 22, in turn, converts the layer 2 SDUs 24 back into either a message 21, which should be identical to the original message 11 that was generated by the application 13 on the first station 10, or a layer 3 signaling message 22a, which should be identical to the original signaling message 12a generated by the layer 3 interface 12 and which is then processed by the layer 3 interface 22. The received message 21 is passed to an application 23 on the second station 20.

[0005] Of particular interest is the layer 2 interface, which acts as a buffer between the relatively high-end data transmission and reception requests of the applications, and the low-level requirements of the physical transmission and reception process. In the following, the term "PDU" is used to indicate layer 2 PDUs; the term "SDU" is used to indicate layer 2 SDUs. Please refer to Fig.2. Fig.2 is a diagram of a transmission/reception process from a layer 2 perspective. A layer 2 interface 32 of a transmitter 30, which may be either a base station or a mobile unit, receives a string of SDUs 34 from a layer 3 interface 33. The SDUs 34 are sequentially ordered from 1 to 5, and are of unequal lengths. The layer 2 interface 32 converts the string of SDUs 34 into a string of PDUs 36. The layer 2 PDUs 36 are sequentially ordered from 1 to 4, and are all of an equal length. The string of PDUs 36 is then sent off to the layer 1 interface 31 for transmission. A reverse process occurs at the receiver end 40, which may also be either a base station or a mobile unit, with a receiver layer 2 interface 42 assembling a received string of layer 2 PDUs 46 into a received string of layer 2 SDUs 44. Under certain transport modes, the multi-layered protocol insists that the receiver layer 2 interface 42 present the SDUs 44 to the layer 3 interface 43 in order. That is, the layer 2 interface 42 must present the SDUs 44 to the layer 3 interface 43 in the sequential order of the SDUs 44, beginning with SDU 1 and ending with SDU 5. The ordering of the SDUs 44 may not be scrambled, nor may a subsequent SDU be delivered to layer 3 until all of the prior SDUs have been delivered.

[0006]

In line transmissions, such a requirement is relatively easy to fulfill. In the noisy environment of wireless transmissions, however, the receiver 40, be it a base station or a mobile unit, often misses data. Some layer 2 PDUs in the received string of PDUs 46 will therefore be missing. Thus, ensuring that the layer 2 SDUs 44 are presented in order can pose a significant challenge. Wireless protocols are carefully designed to address such problems. Generally speaking, there are two broad modes for transmitting and receiving data: acknowledged mode (AM) transport, and unacknowledged mode (UM) transport. For acknowledged mode data, the receiver 40 sends a special layer 2 acknowledging signal to the transmitter 30 to indicate successfully received layer 2 PDUs 46. No such signaling is performed for UM data. For purposes of the present invention, only acknowledged mode data is considered. Please refer to Fig.3 with reference to Fig.1. Fig.3 is a simplified block diagram of an acknowledged mode data PDU 50, as defined in the 3GPP™ TS 25.322 specification, which is included herein by reference. In general, there are two types of PDUs: a control PDU or a data PDU. Control PDUs are used by the layer 2 interfaces 16 and 26 to control data transmission and reception protocols, such as the above-mentioned layer 2 acknowledging signal that is used to acknowledge received data. This is somewhat analogous to the exchange of the signaling messages 12a and 22a of the layer 3 interfaces 12 and 22. However, the layer 2 interfaces 16 and 26 do not interpret or recognize the layer 3 signaling messages 12a and 22a, whereas the layer 2 interfaces 16 and 26 do recognize layer 2 control PDUs, and do not hand layer 2 control PDUs up to the layer 3 interfaces 12 and 22. Data PDUs are used to transmit acknowledged mode data, which is then reassembled and presented to layer 3. The example PDU 50 is a data PDU, and is divided into several fields, as defined by the layer 2 protocol. The first field 51 is a single bit indicating that the PDU 50 is either a data or a control PDU. As the data/control bit 51 is set (i.e., equal to 1), the PDU 50 is marked as an acknowledged mode data PDU. The second field 52 is a sequence number field 52, and is twelve bits long. Successive PDUs 18, 28 have successively higher sequence numbers 52, and in this way the second station 20 can properly reassembled layer 2 PDUs 28 to form layer 2 SDUs 24. For example, if a first PDU 18 is transmitted with a sequence number 52 equal to 536, a sequentially next PDU 18 would be transmitted with a sequence number 52 equal to 537, and so forth. By assembling received data PDUs 50 in their proper sequential order according to their

respective sequence numbers 52, the correct reconstruction of data is ensured. Note that the sequence number 52 enables re-transmitted PDUs 50 to be inserted into their proper sequential position with respect to other received PDUs 50. In this manner, the re-transmission of data is supported. A single polling bit 53 follows the sequence number field 52, and when set indicates that the receiver (i.e., the second station 20) should respond with an acknowledgment status PDU, which is one kind of control PDU, and which will be introduced later. The first station 10 sets the polling bit 53 to 1 to request the second station 20 to send an acknowledgment status control PDU. Bit 54 is reserved and is set to zero. The next bit 55a is an extension bit, and when set indicates the presence of a following length indicator (LI). An LI may be either 7 bits long or 15 bits long, and is used to indicate the ending position of a layer 2 SDU within the layer 2 PDU 50. If a single SDU completely fills the data region 58 of the PDU 50, then the bit 55a would be zero, thereby indicating that no LI is present. In the example PDU 50, however, there are two layer 2 SDUs ending in the layer 2 PDU 50: SDU_1 57a and SDU_2 57b. There must, therefore, be two LIs to indicate the respective ends of the SDU_1 57a and the SDU_2 57b. A PDU following the PDU 50 (i.e., sequentially after, as indicated by the sequence number 52) would hold the LI for SDU_3 57c. The first LI, LI₁, is in field 56a following the extension bit field 55a, and marks the end of the SDU_1 57a. LI₁ 56a has an extension bit 55b that is set, indicating the presence of another LI, LI₂ in field 56b. LI₂ 56b indicates the ending position of the SDU_2 57b, and has an extension bit 55c that is cleared, signifying that there are no more LIs, and that the data region 58 is thus beginning. The data region 58 is used to hold the actual SDU data.

[0007]

Please refer to Fig.4 with reference to Fig.3. Fig.4 is a simplified block diagram of a receiver 64 and a transmitter 65 in a wireless communications system 60. Both the receiver 64 and the transmitter 65 have windows within which they expect to receive the PDUs 50 and transmit the PDUs 50, respectively. The receiver 64 has a receiving window 61 that is delimited by two state variables: VR(R) 62, and VR(MR) 63. VR(R) 62 marks the beginning of the receiving window 61, and VR(MR) 63 marks the end of the receiving window 61. The receiver 64 will only accept PDUs 50 that have sequence numbers 52 that are sequentially on or after VR(R) 62 and sequentially before VR(MR) 63. The sequence number value held in VR(MR) 63 is not considered to be within the

receiving window 61. Similarly, the transmitter 65 has a transmitting window 66 that is delimited by two state variables: VT(A) 67 and VT(MS) 68. VT(A) 67 marks the beginning of the transmitting window 66, and VT(MS) 68 marks the end of the transmitting window 66. The transmitter 65 will only transmit PDUs 50 that have sequence numbers 52 that are within the range of the transmitting window 66, i.e., that are sequentially on or after VT(A) 67, and sequentially before VT(MS) 68.

[0008] The receiving window 61 has a fixed receiving window size. The receiving window size is simply the number of sequence number values spanned by the state variables VR(R) 62 and VR(MR) 63. That is, VR(MR) 63 is always kept a fixed sequence number value distance away from VR(R) 62, which may be represented mathematically as:

[0009]
$$VR(MR) = VR(R) + \text{receiving window size} \quad (1)$$

[0010] Note that, as the sequence number 52 is a 12-bit number, equation (1) is a true 12-bit addition, and thus will suffer from rollover on overflow. Consequently, VR(MR) 63 does not always contain a value that is numerically larger than VR(R) 62. Similarly, the transmitting window 66 has a transmitting window size state variable VT(WS) 66a, which indicates the number of sequence number values spanned by the state variables VT(A) 67 and VT(MS) 68. The state variable VT(WS) 66a has an initial value that is set to a configured transmitting window size, which is supplied by layer 3. As above, this may be represented mathematically as:

[0011]
$$VT(MS) = VT(A) + VT(WS) \quad (2)$$

[0012] And again, the result from equation (2) may suffer from rollover due to overflow. The receiver 64 may explicitly request the transmitter 65 to change the value of VT(WS) 66a. The requested value of VT(WS) 66a, however, cannot be greater than the originally configured transmitting window size, i.e., the size indicated by the transmitter's layer 3.

[0013] As the receiver 64 receives PDUs 50 from the transmitter 65, the receiver 64 will update that value of the state variable VR(R) 62 to reflect the sequentially earliest sequence number 52 before which all preceding PDUs 50 have been successfully received. Put another way, VR(R) 62 always holds the sequence number 52 of the sequentially earliest PDU 50 that the receiver 64 is waiting to receive. Upon the

successful reception of this PDU 50, the receiver 64 advances the state variable VR(R) 62 to the sequence number value 52 of the next PDU 50 that needs to be received, and the state variable VR(MR) 63 is updated using equation (1) accordingly. In this manner, the receiving window 61 is advanced by the receiver 64 as the PDUs 50 stream in from the transmitter 65. It should also be noted that the transmitter 65 may explicitly request the receiver 64 to advance the receiving window 61 with a layer 2 signaling PDU, but this has no bearing on the present invention.

[0014] The transmitting window 66 is advanced when the transmitter 65 receives a layer 2 acknowledgment status PDU from the receiver 64. The layer 2 acknowledgment status PDU holds the most current value of the state variable VR(R) 62, and is sent at periodic intervals by the receiver 24, or in response to an explicit request from the transmitter 65. The acknowledgement status PDU may also indicate PDUs within the receiving window 61 that are known to have been missed (because, for example, sequentially later PDUs have already been received) and which must consequently be re-transmitted. The transmitter 65 will then set the state variable VT(A) 67 equal to the value held in the acknowledgment status PDU, which in effect sets VT(A) 67 equal to VR(R) 62. The transmitter 65 updates the state variable VT(MS) 68 using equation (2) accordingly. In this manner, the transmitting window 66 and the receiving window 61 move forward with each other in lock step, with the transmitting window 66 tending to lag just a bit behind the receiving window 61.

[0015] The transmitter 65 has an additional state variable VT(S) 69. When the transmitter 65 begins transmitting the PDUs 50 that lie within the transmitting window 66, the transmitter 65 begins with a PDU 50 having a sequence number 52 given by the state variable VT(A) 67, and works sequentially forward until it reaches a PDU 50 having a sequence number 52 that is just prior to VT(MS) 68. That is, the transmitter 65 transmits the PDUs 50 in sequence, beginning at VT(A) 67 and ending at VT(MS) 1. The state variable VT(S) 69 holds the sequence number 52 of the next PDU 50 to be transmitted. Thus, the PDUs 50 with sequence numbers 52 on or sequentially after VT(A) 67, and on or sequentially before VT(S)-1 have been transmitted at least one time, and are stored in a retransmission buffer 66b until they are acknowledged by the receiver 64 by way of an acknowledgment status PDU. Note that if a PDU 50 with a sequence number 52 equal to VT(A) 67 is acknowledged, VT(A) 67 is updated to the

next sequentially earliest sequence number value within the retransmission buffer 66b. PDUs 50 with sequence numbers 52 on or after VT(S) 69 have not yet been transmitted by the transmitter 69.

[0016] To insure that the transmitting window 66 advances, the transmitter 65 must, at intervals, request the receiver 64 to send an acknowledgment status PDU. This is termed polling, and is implemented by way of the polling bit 53. When the transmitter 65 determines that it is time to poll the receiver 64, the transmitter 65 will send the next outgoing PDU 50, i.e., the PDU 50 indicated by the state variable VT(S) 69, or a PDU 50 in the retransmission buffer 66b, with the polling bit 53 set to one. Upon reception of any PDU 50 with the polling bit 53 set, the receiver 64 responds by sending an acknowledgment status PDU. The acknowledgment status PDU will contain the most recent value of the state variable VR(R) 62, which the transmitter 65 will subsequently use for the state variable VT(A) 67 to advance the transmitting window 66. Various methods may be used by the transmitter 65 to determine when to poll the receiver 64. The transmitter 65 may, for example, use timer-based polling, in which polling is performed at regular, periodic intervals. Alternatively, the transmitter 65 may use window-based polling, in which the transmitter 65 polls the receiver 64 when a certain percentage of the transmitting window 66 has been transmitted.

[0017] For window-based polling, a polling function that utilizes VT(S) 69 is used to obtain a polling test value "t":

[0018]
$$t = \text{PollingFunction}(\text{VT}(\text{S})) \quad (3)$$

[0019] A polling value is given, which is simply a percentage of the transmitting window 66 that has been sent at least once. For example, one may set the polling value to 60%, indicating that polling is to be performed if 60% or more of the transmitting window 66 has been sent at least once. Polling is triggered if "t" from the above equation (3) exceeds the polling value. When polling is triggered due to "t", the polling bit 53 is set for the next outgoing PDU 50. Triggering polling by setting the polling bit 53 does not tie up any radio resources, as the polling bit 53 is always transmitted anyway, regardless of whether it is set or cleared. However, responding to the polling bit 53 by way of the acknowledgement status PDU does tie up radio resources. Hence, the polling bit 53 should not be set capriciously.

[0020] However, after VT(S) 69 has reached a sufficiently advanced value with respect to VT(A) 67 such that polling is triggered, for those cases that VT(A) 67 has not advanced, any re-transmitted PDU in the retransmission buffer 66b will trigger a poll because the state variables VT(S) 69 and VT(WS) 66a have not changed. This kind of triggering of polling can lead to degradation of the efficient utilization of radio resources (to the subsequent acknowledgement status PDUs in response to the set polling bit 53), and is therefore undesired. Additionally, the exact timing of the updating of the state variable VT(S) 69 can be somewhat ambiguous. For some implementations, VT(S) 69 is updated (i.e., incremented) when the associated PDU 50 is constructed. In other implementations, VT(S) 69 is not updated until the associated PDU 50 is transmitted, or sent to the layer 1 interface. This can lead to difficulties in conformance testing.

Summary of Invention

[0021] It is therefore a primary objective of this invention to provide a method for determining triggering of a polling request in a wireless communications protocol for a transmitter that avoids unnecessary polls, and which is consistent across all implementations.

[0022] Briefly summarized, the preferred embodiment of the present invention discloses a method for determining triggering of a polling request in a wireless communications protocol for a transmitter. The transmitter is capable of transmitting protocol data units (PDUs). Each PDU has an n-bit sequence number. A polling determination method is provided that determines if polling should be performed according to a parameter S that is an n-bit sequence number. Polling is then triggered if a PDU that is next to be transmitted is not a re-transmitted PDU and the polling determination method indicates that polling is to be triggered according to the sequence number of the PDU. The polling determination method uses the equation: $t = ((2^n + 1 + S \cdot VT(A)) \bmod 2^n) / VT(WS)$ to determine if polling should be triggered, where S is the sequence number of the next outgoing PDU.

[0023] It is an advantage of the present invention that the test value accurately returns the percentage of the transmitting window that has been transmitted, and causes the polling bit of a PDU to be properly set regardless of how VT(S) may change from

implementation to implementation. Additionally, by ensuring that the polling bit is set only for PDUs that are being transmitted for the first time, unnecessary polling and response procedures are eliminated, thus ensuring a more efficient use of radio resources.

[0024] These and other objectives of the present invention will no doubt become obvious to those of ordinary skill in the art after reading the following detailed description of the preferred embodiment, which is illustrated in the various figures and drawings.

Brief Description of Drawings

Detailed Description

[0031] In the following description, a communications protocol as disclosed in the 3GPP™ specification TS 25.322 is used by way of example. However, it should be clear to one in the art that any wireless communications protocol that requires polling to acknowledge the reception of transmitted data may utilize the poll-triggering method of the present invention. It should be further noted that transmitters and receivers in the following detailed description can include cellular telephones, personal data assistants (PDAs), personal computers (PCs), or any other devices that utilize a wireless communications protocol.

[0032] It is the method of the present invention to determine triggering of a polling request for a transmitter only for PDUs that are not being re-transmitted, and by using the following equation:

[0033]
$$t = \{(2^n + 1 + S \cdot VT(A)) \bmod 2^n\} / VT(WS) \quad (4)$$

[0034] Retransmitted PDUs may be transmitted with their associated polling bits 53 set to one by other polling triggers, such as a "Last PDU in retransmission buffer" event. However, re-transmitted PDUs never trigger a polling operation by the present invention. The term "S" within equation (4) is the sequence number of a PDU whose polling bit 53 is to be set or cleared based upon "t". The term "n" is the bit-size of the sequence number "S". In the preferred embodiment, the sequence number "S" is a 12-bit value, and hence the term "n" is 12.

[0035] To better understand equation (4), please refer to Fig.5. Fig.5 is a simplified block diagram of a wireless communications system 70 that utilizes the method of the present invention. The wireless communication system 70 includes a receiver 80 and a transmitter 90. Both the transmitter 90 and the receiver 80 utilize a 3-tiered communications protocol. In the transmitter 90, a layer 3 interface 93 passes layer 2 service data units (SDUs) 93a to a layer 2 interface 92 for transmission. The layer 2 interface 92 composes the SDUs 93a into layer 2 protocol data units (PDUs) 92a that are passed to the layer 1 interface 91 for transmission. The PDUs 92a have a format that is identical to that discussed in the Description of the Prior Art, and thus need not be detailed any further here. In particular, though, each PDU 92a has an n-bit sequence number 52 that identifies the sequential order of the PDU 92a in a stream of transmitted PDUs 92a. For the preferred embodiment, n is 12, and thus the sequence numbers for the PDUs 92a have a cyclical range from zero to 4095. Each PDU 92a also has a polling bit 53 that may be set by the transmitter 90 to poll the receiver 80. As discussed in the prior art, the receiver 80 responds to a set polling bit 53 with an acknowledgment status PDU so that the transmitter 90 may advance its transmitting window 94.

[0036] The transmitting window 94 is defined by state variables VT(A) 95, VT(WS) 96 and VT(MS) 97. The transmitter 90 will only transmit PDUs 92a with sequence numbers 52 that are within the transmitting window 94. The state variable VT(A) 95 marks the

beginning value of the transmitting window 94. The state variable VT(WS) 96 marks the size of the transmitting window 94, which is simply the number of sequence number values 52 spanned by the transmitting window 94. The state variable VT(MS) 97 marks the end of the transmitting window 94, and is thus just the sum of VT(A) 95 and VT(WS) 96. Due to overflow, the value held within VT(MS) 97 need not be greater than a value held within VT(A) 95. Finally, a state variable VT(S) 98 holds the sequence number 52 of a PDU 92a that is next in line to be transmitted. VT(S) 98 will always be sequentially on or after VT(A) 95, and sequentially on or before VT(MS) 97. The state variables VT(A) 95, VT(WS) 96, VT(MS) 97 and VT(S) 98 are identical in function to those discussed in the Description of the Prior Art.

[0037] The transmitter 90 also includes a calculation unit 99 that is used to calculate a test value t 99a. The value of t 99a is compared against a polling value 93b, that is supplied by the layer 3 interface 93, to determine if the transmitter 90 should poll the receiver 80. The polling bit 53 is set in a subsequently generated and transmitted PDU 98p if polling is to be performed. The test value t 99a is used for window-based polling, and to generate a value for t 99a the calculation unit utilizes the state variables VT(A) 95, VT(WS) 96, the sequence number S 98s held within the PDU 98p, and equation (4). The polling value 93b indicates a transmission percentage of the transmitting window 94, i.e., the polling value 93b indicates the percentage of PDUs 92a in the transmitting window 94 that have been transmitted by the transmitter 90. If the value of t 99a exceeds or equals the polling value 93b, and the PDU 98p is not a re-transmitted PDU 92a, then a polling request is triggered by setting the polling bit 53 of the PDU 98p to one. That is:

[0038] 1) If the PDU 98p is a re-transmitted PDU 92a, then the polling bit 53 for the PDU 98p is not required to be set to one by the present invention. If the PDU 98p is being transmitted for the first time, then the polling bit 53 is set according to the test value t 99a and the polling value 93b.

[0039] 2) If required, the test value t 99a is generated using equation (4) above. The parameters for equation (4) are obtained from the state variables VT(A) 95, VT(WS) 96, the sequence number S 98s of the PDU 98p under consideration, and the bit-size n of the sequence number S 98s.

[0040] 3)Only if the test value t 99a equals or exceeds the polling value 93b, and the PDU 98p is not a re-transmitted PDU 92a, should the polling bit 53 for the PDU 98p be set to one to trigger polling.

[0041] Please refer to Fig.6 with reference to Fig.5. Fig.6 is a flow chart of the method of the present invention, which is implemented by the calculation unit 99 to determine if polling should be triggered by the transmitter 90. The steps are explained below:

[0042] 100:Obtain a PDU 98p for which the polling bit 53 is to be set or cleared.

[0043] 110:If the PDU 98p obtained in step 100 is a re-transmitted PDU 98p, then go to step 180. Otherwise, proceed to step 120.

[0044] 120:Obtain the current values for the transmitting window 94, which include the values from the state variables VT(A) 95 and VT(WS) 96, and additionally extract the sequence number S 98s from the PDU 98p obtained from step 100.

[0045] 130:A first value x is computed. The value x is $(2^n + 1)$ added to the difference of the sequence number S 98s and the state variable VT(A) 95. The value of n is the bit size of the sequence number S 98s, and thus in the preferred embodiment is 12. Consequently, 4097 is added to (S VT(A)).

[0046] 140:A second value y is computed. The value of y is the modulus of the first value x with 2^n . The second value y is thus $x \bmod 4096$.

[0047] 150:The test value t 99a is obtained by dividing the second value y by the state variable VT(WS) 96. The test value t 99a indicates the current transmission percentage of the transmitting window 94 in fractional form with respect to the PDU 98p.

[0048] 160:Compare the test value t 99a to the polling value 93b. As the polling value is stored as a percentage in the form of zero to 100, the value of t 99a is multiplied by 100 to perform this comparison.

[0049] 170:If the transmission percentage as represented by t 99a is greater than or equal to the polling value 93b, then polling is triggered for the transmitter 90. The polling bit 53 for the PDU 98p is set to one.

[0050] 180:If the transmission percentage as represented by t 99a is less than the polling

value 93b, or the PDU 98p is a re-transmitted PDU 98p, then no polling is required.

[0051] 190:End of polling determination method. For a next PDU 98p, the process is repeated from step 100.

[0052] In contrast to the prior art, the present invention utilizes a calculation unit to compute a test value t according to the equation:

[0053]
$$t = \{(2^n + 1 + S \cdot VT(A)) \bmod 2^n\} / VT(WS)$$

[0054] The above formula accurately yields the transmission percentage of the transmitting window of the transmitter with respect to the PDU being considered so that the transmitter will accurately trigger a polling request. However, polling is only performed if the PDU under consideration in the above equations is not a re-transmitted PDU. Polling is not triggered with re-transmitted PDUs. In this manner, unnecessary usage of radio resources is avoided. A more efficient wireless transmission system is thereby ensured. By using the actual sequence number S 98s embedded within the PDU 98p, rather than the current value of the state variable VT(S) 98, implementation ambiguities of the value of VT(S) 98 are avoided. Conformance testing is consequently made easier.

[0055] Those skilled in the art will readily observe that numerous modifications and alterations of the device may be made while retaining the teachings of the invention. Accordingly, the above disclosure should be construed as limited only by the metes and bounds of the appended claims.
